

# Quantifying and measuring climate, health and gender co-benefits from clean cooking interventions

BERKELEY AIR  
MONITORING GROUP

August 6<sup>th</sup>, 2020

# Project activities: Field Study on Quantifying and Measuring Climate, Health and Gender Co-Benefits from Clean Cooking Interventions

- Select project implementer
- Review methodologies
- Design field study to tech methodologies
- Test methods with field study
- Report results and recommendations

# Implementing partner selection

- Competitive process:
  - Technology considerations
    - Low emissions fuel/stove technology (Tier 3 emissions or better)
    - Safe and durable
  - Programmatic considerations
    - Meet household cooking needs (high potential for displacement of traditional stoves)
    - Sustainable fuel supply
    - Focus on SSA
  - 13 applicants

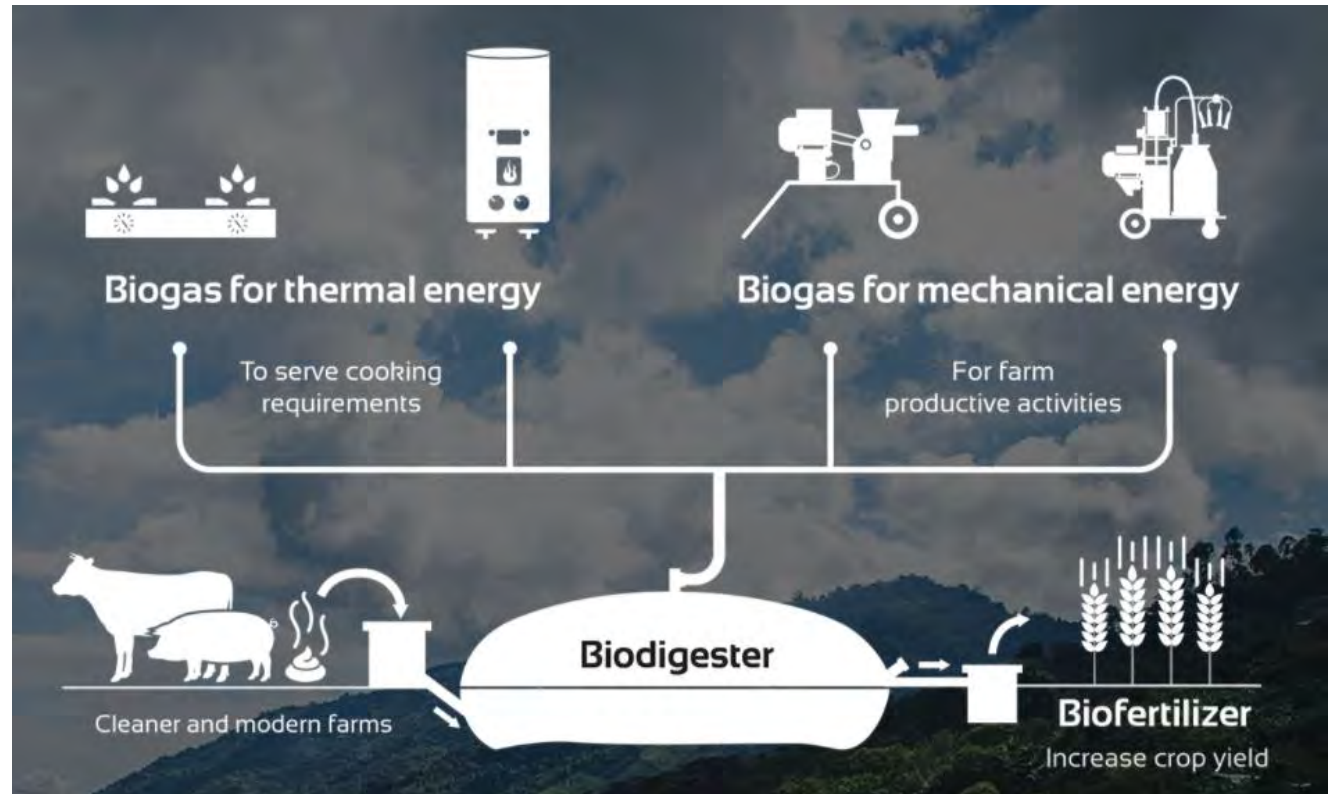

# Selected partner

Manufactures, sells, installs and provides financing for biodigester systems for small and medium-scale farmers.

A choice of one or two burner stoves included in biodigester package.

2019 Ashden Award winner

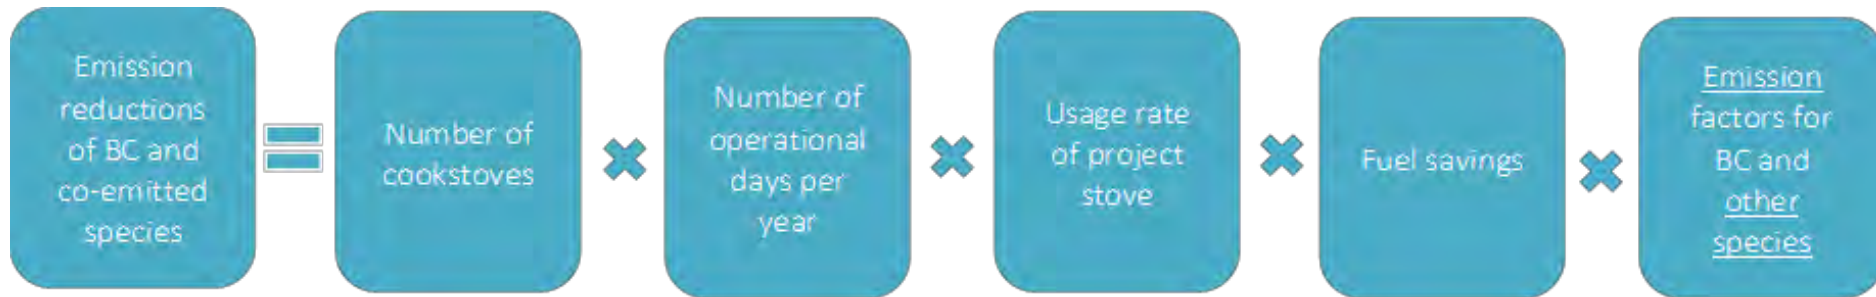

# Methodology review

CRITERIA	PURPOSE
Cost Effectiveness	While the chosen methodologies and approaches will be robust and have environmental integrity embedded in their design, profitability for practitioners and users will be essential to their usefulness. Among others, the key determining factors of their cost-effectiveness include: (i) monitoring requirements, such as field or lab-based testing, surveys, and minimum sample size, and (ii) enabling infrastructure, including any needed monitoring expertise, availability of testing facilities across geographies, monitoring equipment costs, and other resources.
Scalability	Methodologies and approaches will be assessed for their potential to help projects and programs scale-up effectively.
Replicability	The reference methodologies and approaches should be replicable. Projects in different geographies, of different scales, and using a range of ECCH interventions should all be able to use these methodologies.
Robustness	The methodologies and approaches will be assessed for robustness for quantification and verification of the impact and whether they have been developed in consultation with a wide variety of stakeholders, including subject experts.
Compatibility	Ideally, application of the methodology should be compatible with methods for verifying other impacts.
Operational Feasibility	The operational feasibility of bringing the methodologies and approaches up to scale will be assessed.

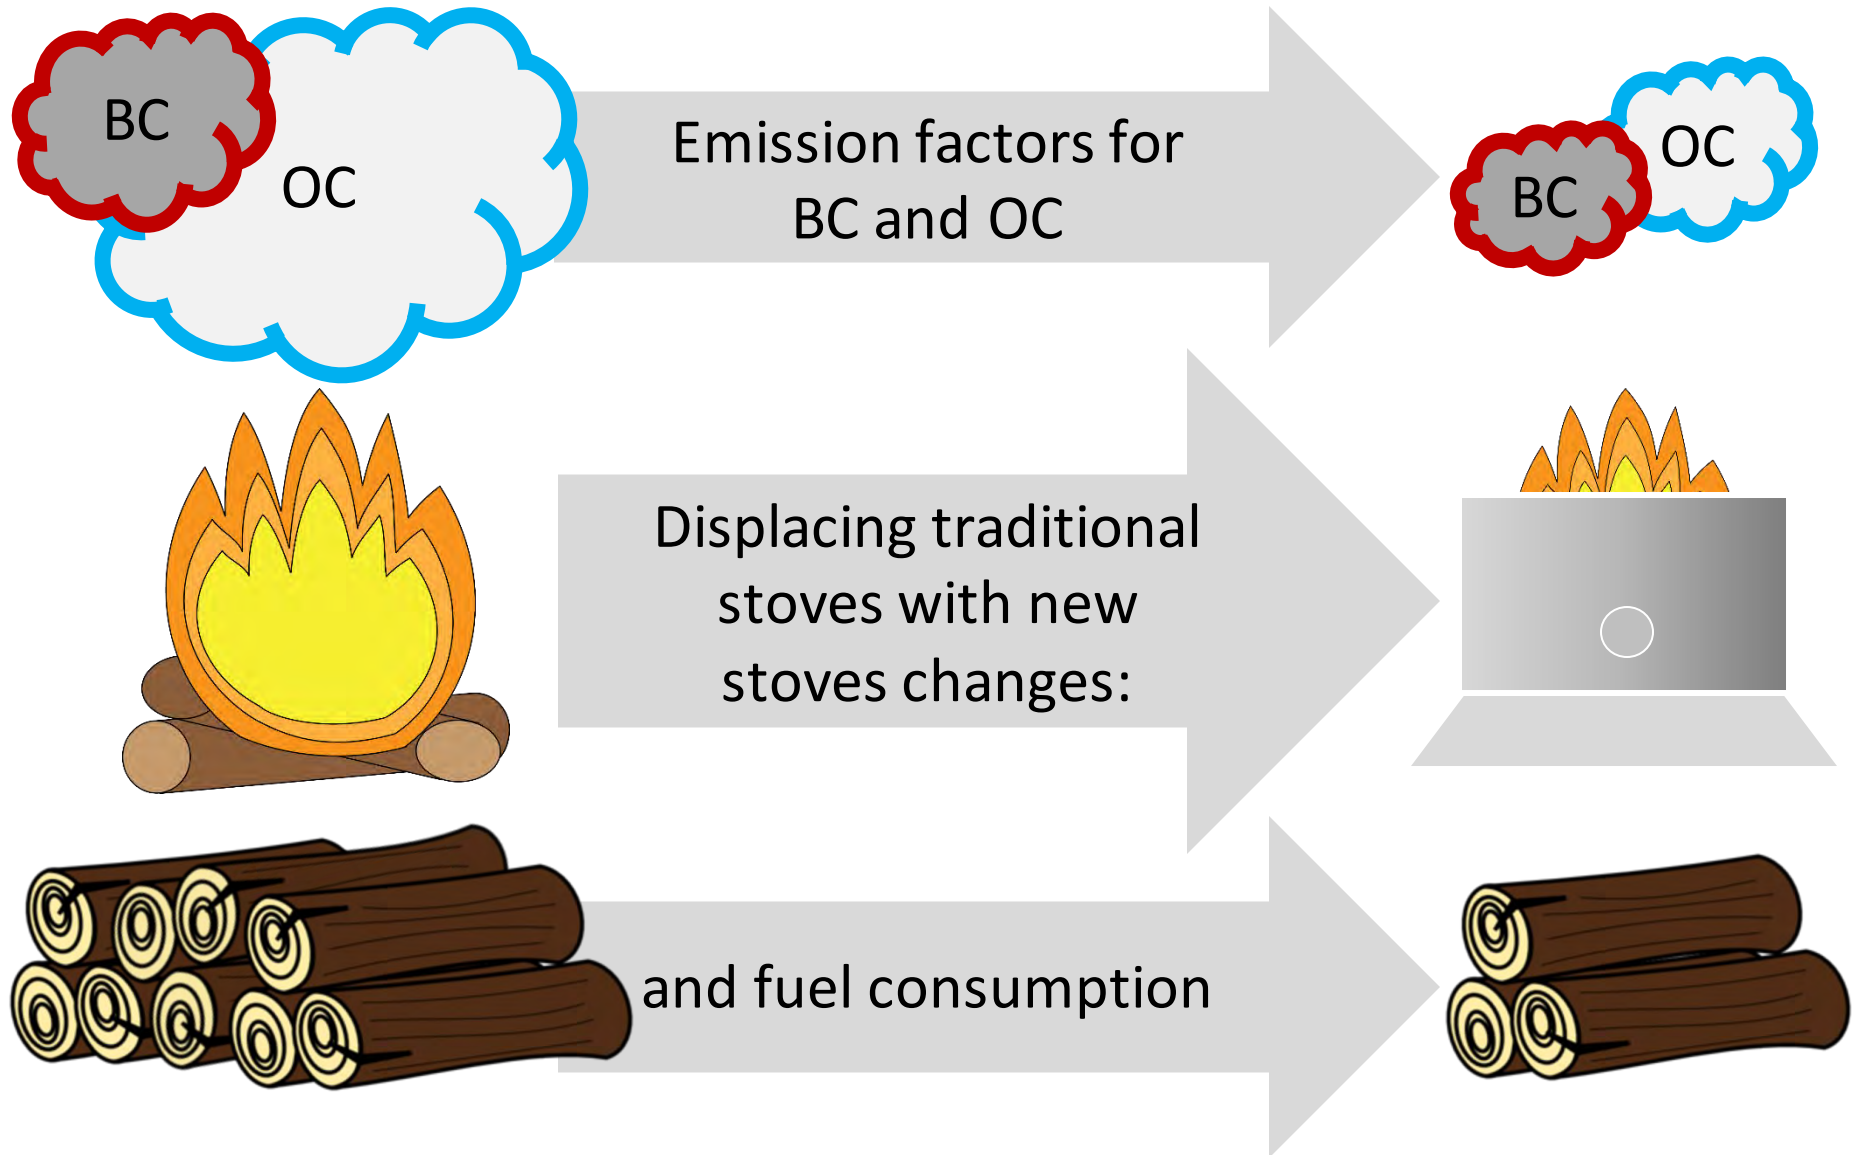

# Climate impacts (short-term)

The Gold Standard methodology “[Quantification of climate-related emission reductions of Black Carbon and Co-emitted Species due to the replacement of less efficient cookstoves with improved efficiency cookstoves](#)”

# Factors affecting the warming impact from aerosol emissions

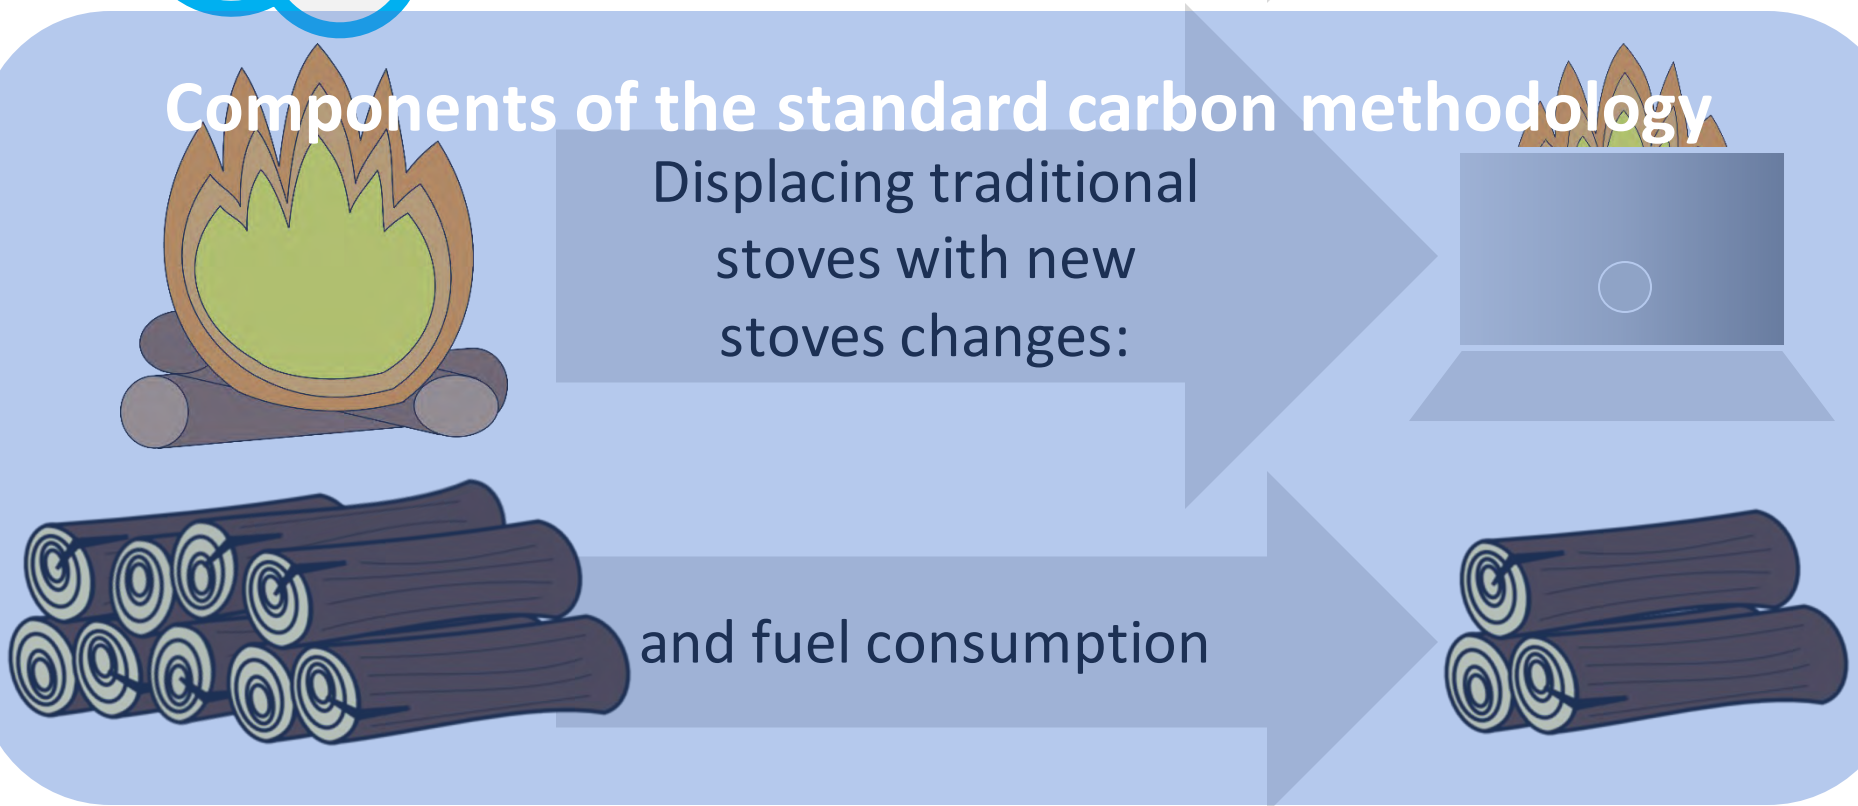

Other factors impacting climate forcing: Extent of displacement, geography, weather, modeling assumptions, co-emitted pollutants, brown carbon, fuel renewability, etc...

# Factors affecting the warming impact from aerosol emissions

## Components specific to black carbon methodology

## Components of the standard carbon methodology

Other factors impacting climate forcing: Extent of displacement, geography, weather, modeling assumptions, co-emitted pollutants, brown carbon, fuel renewability, etc...

# Methods for estimating emission factors

- Current: measure in the field (expensive/technical), or laboratory (accurate?) and adjust if needed based on a sample of simple concentration measurements.
- Recommendation for alternative approach: Use literature values from recent field studies (not available at time of original methodology development).
- We will compare the results of using both approaches.
- Use of technology-specific defaults could result in less-expensive monitoring and more accurate results

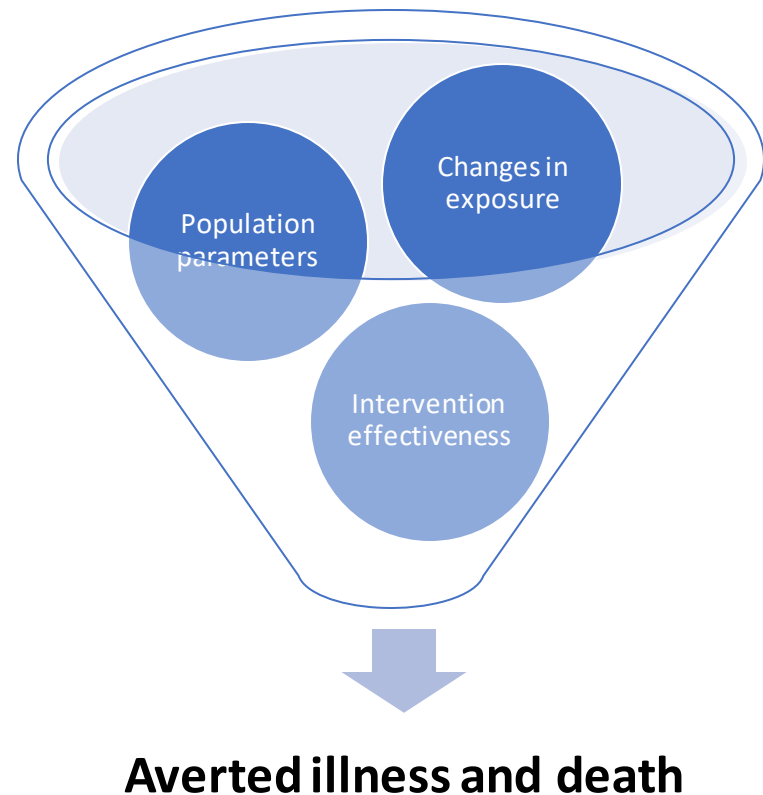

# Health Methodologies

## Dr. Sumi Mehta

---

Despite widespread interest, only one methodology (Gold Standard) applied to date

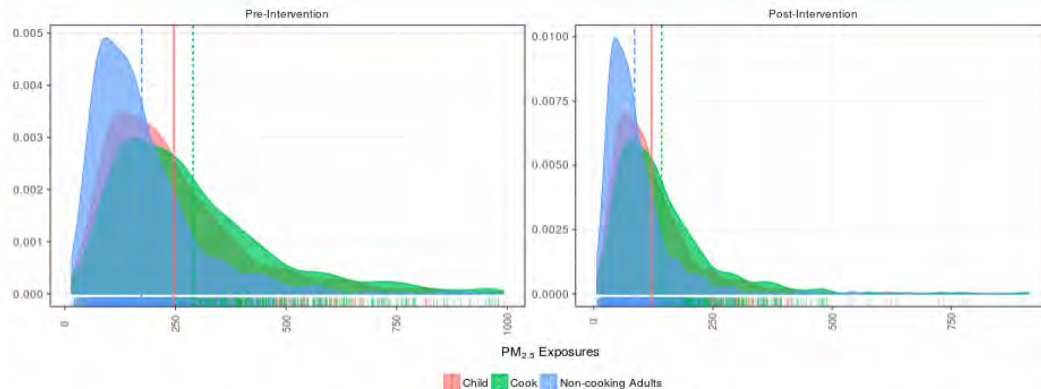

Approach: estimate averted illness and death expected from reduced air pollution exposure

# Methodology uses HAPIT tool to estimate impacts

<https://householdenergy.shinyapps.io/hapit3/>

## Exposure-related Inputs

Simulated PM<sub>2.5</sub> exposures based on user-input pre- and post-intervention exposure means and standard deviations. Pink, green, and blue bars represent distributions for children, primary cooks, and non-cooking adults, respectively. Dashed lines are the per-group means of the draws from the distributions. Vertical ticks along the x-axis are individual points making up the distribution.

**Instructions.** Enter your mean pre- and post-intervention PM<sub>2.5</sub> exposures and standard deviations. If you do not have standard deviations, click the 'Default SD' button to set the SDs to 0.70 times the input exposures. **After entering or changing values, click 'Update Exposures'.** Do not leave any fields empty.

# Lao PDR Case Study

Averted burden of disease calculated assuming  $PM_{2.5}$  exposure reduced from 119 to 77  $\mu g/m^3$  in 25,000 households, no stacking, 3-year stove lifetime, and 75% usage

Source: Smith K.R et al 2015.

# LAO PDR Case Study: Summary of Recommendations, by Phase

## Methodology Overview

### Phase I: Planning

#### Step 1: Set community expectations

- Work with community leaders to establish appropriate dissemination methods
- Ascertain willingness to forego the revenue from aDALYs sold in exchange for lower cost interventions

#### Step 2: Make clean cooking system choices

- Interventions chosen should match local cooking patterns and fuel availability
- For advanced biomass stoves, high-quality independent lab tests should be conducted in addition to usage, stacking, and durability field studies
- Field fuel efficiency assessment recommended

Months: 1-2

### Phase II: Validation

#### Step 3: Pre-dissemination monitoring

- Household surveys
- Measurements of personal exposure, kitchen air pollution (KAP), stove use monitoring, and ambient air pollution (AAP), if applicable

#### Step 4: Stove dissemination

- Encouraging replacement of traditional stoves and proper usage of intervention stove

#### Step 5: Post-dissemination monitoring

- Repeat measurements in Step 3 to establish impacts of the intervention stove

#### Step 6: Evaluation of exposure and health changes

- Determine personal exposure changes for cooks and stove usage trends
- Assess any changes in AAP
- Run HAPIT model to estimate potential health changes and averted DALYs

Months: 3-4

### Phase III: Verification

#### Step 7: Health investment verification

- If potential health benefits are sufficient (per validation), apply for aDALY credits for existing or new dissemination
- Demonstrate exposure reductions over time per verification protocol
- Sampling should include personal exposure in households with and without intervention
- First verification at 6 or 12 months, annually thereafter

Month 6 or 12, then annually

# How Could Other Methodologies Be Applied to Measure Health Benefits of Clean Cooking Interventions?

Application Methodology Framework	Example of Application	Example of Application for ECCH Interventions
W+ health method	One project on food, fuel, and livelihoods includes focus on health benefits of no pesticide, clean water (nothing on air pollution)	Self-reported general health and problems due to air pollution (indoor and outdoor)
Reductions in personal exposure to PM <sub>2.5</sub>	Health impact assessments for air pollution	Reductions in personal exposure to PM <sub>2.5</sub>
Measures consistent with health sector and health systems performance	Increased use and quality of health services received	N/A: Measures are too distal from intervention
Measurement of change in health expenses	Water and sanitation interventions	Reduced household energy-related health expenditures
Measurement of direct health outcomes or changes in health-seeking behavior (health care facility-based measures)	Number of children immunized; number of women receiving antenatal care visits	Reduced visits to health care facility for respiratory illness; improved lung function
Self-reported health indicators and outcomes (based on validated questions, e.g., DHS)	Reduced diarrheal disease associated with improved water and sanitation	Reduced respiratory illness in young children

ADALYs methodology is resource intensive but remains the best option at present.

Criteria	ADALYs methodology	Personal exposure to PM <sub>2.5</sub>	Measures consistent with health sector / health systems performance	Measurement of change in health expenses	Measurement of direct health outcomes / changes	Self-reported health indicators and outcomes
<b>Cost-effectiveness</b>	resource intensive	resource intensive	depends on the current capacity of the health system → can be cost-prohibitive	Inexpensive on a per household basis.	depends on the current capacity of the health system	inexpensive on a per household basis
<b>Scalability</b>	Yes	Yes	Yes	Yes	Yes	Yes
<b>Replicability</b>	Yes	Yes	Possibly	No	Yes	No
<b>Robustness</b>	Yes	Yes	No	No	No	No
<b>Compatibility</b>	Yes	No	No	No	No	No
<b>Operational feasibility</b>	best option at present → integrates exposure with epidemiologic evidence	most accurate risk indicator, but inconsistent with conventional health sector outcomes	not relevant to this sector	only feasible at an extremely large scale	only feasible at extremely large scale	unreliable measures, results highly influenced by external factors which are difficult to predict and quantify

# Gender Methodologies

## Dr. Joni Seager

---

# Overarching goal

To improve the evidence base on the gendered dynamics of adoption of cleaner cookstoves:

- are there identifiable gender specific co-benefits?
- more specifically, can adoption of cleaner cookstoves contribute to/enhance gender equality & women's empowerment?

# An audacious leap!

**Common premise of established methodologies and literature:**  
gender co-benefits and women's empowerment might be leveraged by,

- time savings (relieving time poverty)
- reduction in drudgery associated with traditional cooking (primarily fuelwood collection)

**Foundational proposition:**

the improved cookstove might be an “index intervention” that produces time savings, which in turn, may enable and catalyze women's empowerment and gender equality

# Established conceptual and methodological frameworks

METHODOLOGY	METHODOLOGY TYPE	ASSESSMENT APPROACH
<b>Women Organizing for Change in Agriculture and Natural Resource Management (WOCAN)/ W+ methods</b>	Framework & Measurement	<p>Survey algorithm to convert measured results and outcomes to women's empowerment "credits"</p> <p>Requirements and guidelines to enable the design of project-specific monitoring and a quantification approach for gender claims</p>
<b>Gold Standard Gender Equality Requirements and Guidelines</b>	Framework	<p>Survey and other methods</p> <p>Requirements and guidelines to enable the design of project-specific monitoring and a quantification approach for gender claims</p>
<b>Clean Cooking Alliance and International Centre for Research on Women (ICRW) Social Measurement Impact System</b>	Measurement & Framework	<p>Survey by phone and/or in person</p> <p>Customized survey templates for both cookstove and fuel value chain and end users</p>
<b>The Women's Empowerment in Agriculture Index (WEAI)</b>	Measurement index	Survey and provision for time diary

# Mixed methods approach

## Time saved:

quantitative/time trackers; qualitative self-reporting and survey

“So what?” of time savings and satisfaction (how women do or could use their time, probing for links to empowerment opportunities):

qualitative semi-structured interviews, focus groups

Reduction of “drudgery”:

qualitative, semi-structured interviews, focus groups

Current state and changes to gendered dynamics of cooking and cooking technology:

qualitative, semi-structured interviews, focus groups

# Contributions

- expand the currently thin field-based evidence base on gender co-benefits of improved cookstoves
- establish a foundation for specifically empowerment-focused longitudinal studies

# Contributions

- engage with complexities of the global clean-cookstoves gender agenda:
  - problem and priority definition;
  - contradictions in foregrounding improved domestic appliances as a pathway to women's empowerment;
  - global investor monetization of women's unpaid labor as a solution for global problems.

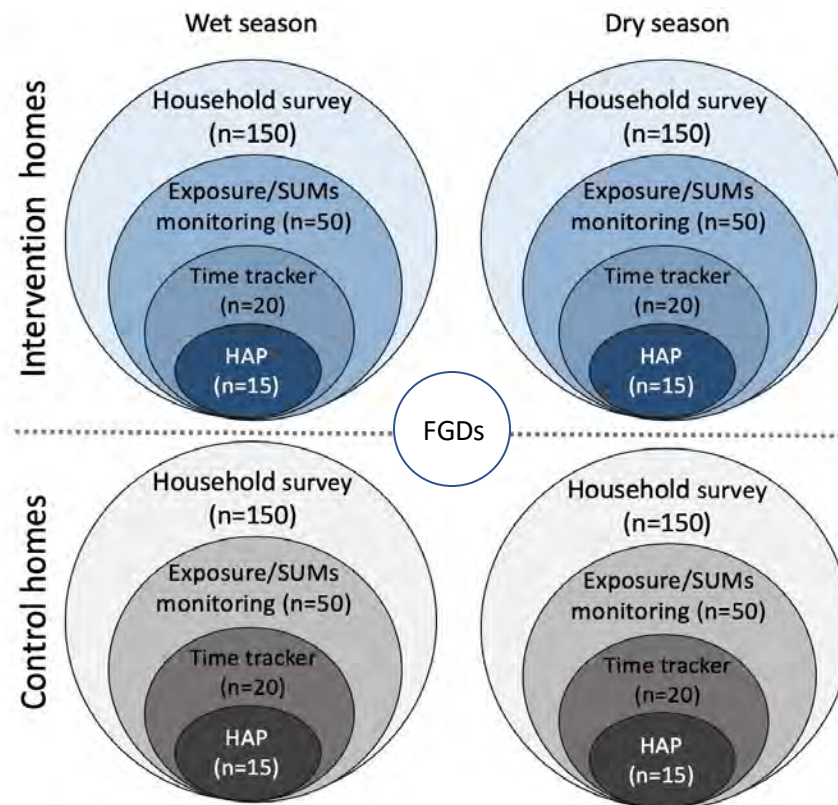

# Next steps

## Dr. Michael Johnson

---

# Field Testing

Aim: demonstrate the measurement and quantification process of the three co-benefits applying the methodologies and recommendations from the review process.

Thank you
